54 Antimicrobial fabric for surgical drape.

57 A nonwoven fabric having antimicrobial properties suitable for use as a surgical drape is disclosed. The fabric is bonded with a bonder that contains a polyhexylmethylenes biguanide salt as the antimicrobial agent. The bonder may also contain a rewetting agent.

EP 0 136 900 A2

Antimicrobial Fabric for Surgical DrapesField of the Invention

5 This invention relates to nonwoven fabric which possesses  
antimicrobial properties and is useful in the manufacture  
of surgical drapes. The nonwoven fabric is treated with  
an antimicrobial agent which has activity against a broad  
spectrum of Gram negative and Gram positive bacteria and  
10 which will not become inactivated by contact with blood  
serum.

Background of the Invention

Surgical drapes are used during surgical procedures to  
isolate the patient from the operating room personnel and  
15 the environment of the operating room. The surgical  
drapes were originally made of woven textile fabrics, but  
these fabrics have substantially been replaced by nonwoven  
fabrics. The advantages of the nonwoven fabrics are that  
they can be made repellent to retard or prevent liquid  
20 strike-through from the upper or the contaminated surface  
of the drape through the drape to the patient. The  
passage of liquid through a surgical drape is considered  
to be a source of bacterial contamination to the patient,  
possibly resulting in infection. In most disposable  
25 surgical drapes, the area immediately surrounding the  
operative site in the drape is reinforced with additional  
layers of nonwoven repellent fabric or with a combination  
of an absorbent fabric and an impervious plastic film.  
The use of an absorbent fabric or other material such as  
30 an absorbent foam around the operative site is advan-  
tageous because the surface of these materials helps to  
prevent fluid run off from the area surrounding the  
operative site into the operative wound sit . Although

the use of these absorb nt materials offers an advantage, there is still a possibility that some fluid will flow into the wound site when the absorbent material has become saturated or if the fluid is present in greater quantity than the absorbent capacity of the absorbent material. This fluid could be contaminated with bacteria or may contact bacteria on the surface of the drape and become contaminated. Bacteria-contaminated fluid flowing into the wound site could cause post-operative infection problems for the surgical patient. For this reason surgical drapes which are treated with antimicrobial agents have been considered to be desirable.

Although there are large numbers of antimicrobial agents available to the manufacturer of surgical drapes, these antimicrobial agents have not been found to be suitable for this particular use for a number of reasons. The antimicrobial agent should be active against a broad spectrum of both Gram positive and Gram negative bacteria. Many of the antimicrobial agents are cationic in nature and react with the anionic surfactants that are commonly used in the binder systems to bind the fibers in the nonwoven fabrics. This inactivates the antimicrobial and renders it useless for the intended purpose. Other antimicrobial agents are not effective in contact with blood serum. Although the antimicrobial is effective in contact with other fluids, the presence of blood serum on the surface of the drape inactivates the antimicrobial and renders it useless. In addition, some antimicrobials are considered to be toxic to humans and, if they are capable of leaching from the nonwoven fabric in the presence of fluids found in the operating room, such as saline solutions, these antimicrobials are not considered to be desirable for use in surgical drapes. Other antimicrobials react with the binders or finishes in the fabric and form toxic adducts.

There have been prior attempts to incorporate antimicrobial agents into materials that will be useful for surgical drapes and similar products. U.S. Patent 3,310,459 suggests the formation of a latex impregnated, water-laid sheet for use as a surgical drape. An antimicrobial agent or bactericidal substance is suggested to be incorporated in the water used to form a cellulose web. The web is formed on normal paper-making equipment. A web formed in this manner does not have the properties desired as a fabric for use as a surgical drape.

U.S. Patent 3,521,625 suggests the use of a formaldehyde precursor in various absorbent products such as surgical dressings, disposable diapers and surgical drapes. When the formaldehyde precursor is contacted with water, formaldehyde is released which inhibits bacteria proliferation. Formaldehyde is not considered to be a desirable antimicrobial for contact with human skin.

In addition, the particular antimicrobial agent used in the present invention, polyhexamethylene biguanide, has been suggested as an antimicrobial that has some utility in the treatment of textile materials. U.S. Patents 2,336,605; 2,990,425; 4,022,836; 2,863,919 disclose this utility.

A surgical drape is commercially available which contains an antimicrobial on the surface of the drape. The antimicrobial agent is a silicone quaternary ammonium salt. This surgical drape does not meet all of the desirable requirements for a product of this type because the antimicrobial is inactivated to a large degree in the presence of blood, which is commonly found on the surface of surgical drapes during surgical procedures. The efficacy of the antimicrobial agent used in this product is significantly diminished in the presence of blood.

Summary of the Invention

The present invention provides a surgical drape containing antimicrobial agents which are not inactivated by blood serum and which have a very low saline extractability level and, therefore, have low toxicity to the patient. The surgical drape of the present invention is made with a cellulose-containing, nonwoven fabric which is bonded with a binding agent which contains little or no anionic surfactant or is made with a nonionic surfactant. The fabric contains a polyhexamethylene biguanide salt as the antimicrobial. In addition, the surgical drape may be treated with a rewetting agent which is an amphoteric surfactant to insure that the surface of the surgical drape has absorbent properties if absorbency is desired.

In addition to its use as an absorbent component in a surgical drape material, the antimicrobial-treated nonwoven fabric of the present invention can also be used for other applications in an operating room. It can be employed as an instrument wrap, a table cover and, if repellent treated, as a water-repellent drape material. When used in the present application, the term "surgical drape" is intended to apply to all such uses of the present antimicrobial-treated nonwoven fabric.

Detailed Description of the Invention

The present invention finds its greatest application in disposable surgical drapes. These drapes are made with a nonwoven fabric which is generally treated with a water-repellent agent. The treatment with a water-repellent agent provides resistance to liquid strike-through, particularly water, through the surface of the drape when the drape is in use. It is believed that the passage of liquid through the drape can carry bacteria from the upper surface of the drape into contact with the body of the patient and offset the possibility of introducing foreign

bacteria into the patient, especially at the wound site of the surgical procedure. The surgical drapes are often constructed with a fenestration preformed in the drape. The fenestration is the opening through which the surgical procedure will be performed. There is generally a reinforcement around the fenestration to provide additional resistance to liquid penetration which might occur because of the presence of fluids in the area of the fenestration. The upper surface of the reinforcement area is generally made with an absorbent surface so that liquid will be absorbed on the surface to reduce the tendency of liquid to flow into the operative site. The lower surface of the reinforcement area is usually liquid-impervious film to prevent liquid strike-through to the operative site.

As previously indicated, attempts have been made to introduce antimicrobial agents into this absorbent material to lessen the possibility of bacteria being transferred into the wound site. The selection of an antimicrobial that can be used for this purpose is complicated by the chemical nature of the binders that are used in the nonwoven fabrics which form the drape. Many antimicrobials are cationic in nature and the binders used in the manufacture of nonwovens generally contain an anionic surfactant which is used as the emulsifying or dispersing surfactant in the manufacture of the polymeric binder. The cationic antimicrobial agents and the anionic surfactants are not only incompatible but often interreact to form adducts which may in themselves have toxic properties. It is, therefore, not possible to make a simple selection of any nonwoven fabric material and add one of the many available antimicrobials to the nonwoven fabric to form an effective bactericidal surface on the disposable drape.

The antimicrobial nonwoven fabric of the present invention is particularly useful as the fabric on the reinforcement area of a surgical drape. The nonwoven fabric may be made from any of the standard nonwoven fabric manufacturing processes. The nonwoven fabric used in the manufacture of surgical drapes generally weighs between 40 and 100 grams per square meter. The fabric generally contains some amount of cellulosic fiber, either in the form of regenerated cellulose, i.e., rayon, or woodpulp fibers. These fibers have absorbent properties which are desirable for the reasons given above. The nonwoven fabric may also contain synthetic fibers such as polyester or polypropylene as is commonly found in nonwoven fabrics. The binder system that is used for these nonwoven fabrics must be one that contains little or no anionic surfactant in the formulation of binder or in the formulation of the polymer material on which the binder system is based. An excellent binder material that can be used for the purpose of the present invention is a copolymer of ethylene and vinyl acetate. This binder system is available as a dispersion in polyvinyl alcohol with no surfactant in the system. The binder is also available dispersed in water with a nonionic surfactant. Either form of the ethylene vinyl acetate polymer is suitable in the practice of the present invention. The binder generally contains approximately 70% ethylene and 30% vinyl acetate and may contain small amounts of other ingredients such as crosslinking agents or other additives. Other binding systems that can be used are based on styrene butadiene polymers and acrylate polymers in which the anionic surfactant has been removed from the polymer.

The method of application of the binder to the formed web can be by any commonly available system. It is, however, preferred to incorporate all of the binder and the

-7-

antimicrobial agent along with the rewetting agent into a mixture and spray this mixture onto a preformed web to give better control of the amount of antimicrobial in the finished product. The antimicrobial can also be applied by printing in a print pattern on one or both surfaces of the web. The binder is then cured by the usual curing techniques used in the manufacture of such nonwoven fabrics.

- 10 The antimicrobial agent that is used in the present invention is a commercially available antimicrobial polyhexamethylene biguanide hydrochloride. The stoichiometric formulation for this material is  $C_8H_{18}N_5Cl(C_8H_{18}N_5Cl)_n$  where n is between 4.5 and 6.5. The structural formula is:

- 20 This material is generally known as PRMB and is available from ICI North America as an aqueous liquid containing approximately 20% solids. It has antimicrobial activity against a broad spectrum of both Gram negative and Gram positive bacteria.

If it is desirable to provide absorbent characteristics to the nonwoven fabric, it is necessary to include a rewetting agent or rewetting surfactant in the formulation.

- 30 This material is preferably an amphoteric surfactant so that it will not interfere with the antimicrobial agent. Suitable nonionic rewetting agents include betaine surfactants, nonylphenoxypoly (ethyleneoxy) ethanol, polyethylene glycol esters and sucrose fatty acid esters.
- 35 The preferred rewetting agent is cocamidopropyl betaine.

It is particularly important in the practice of the present invention to insure that the amount of antimicrobial agent on the surface of the nonwoven web is sufficient to give the desired bactericidal activity but is not so great to pose a problem in the event that some of the antimicrobial is leached from the surface of the fabric when this fabric is wetted with an operating room liquid. The antimicrobial must be effectually tied into the surface of the web either by some attraction to the fibers in the web or to the binder itself. The amount of the antimicrobial that can be extracted from the surface of the web by leaching with a saline solution should be less than approximately 80 parts per million and preferably less than 50 ppm. Saline extraction levels of the antimicrobial greater than 80 ppm may cause problems of toxicity which must be avoided.

A typical formulation of binder, antimicrobial and rewetting agent would contain the following (amounts are in parts by weight):

	<u>Wet Weight</u>	<u>Dry Weight</u>
Ethylene Vinyl Acetate	157	86.35
25 PHMB	4.0	0.80
Lexaine C	4.8	1.44
NH <sub>4</sub> CL (crosslinking agent)	0.57	0.57
Water	<u>302</u>	<u>          </u>
TOTAL	468.57	89.16

30

The formulation is thoroughly mixed and is then applied to an unbonded, nonwoven web during the manufacturing process of the nonwoven fabric. The formulation can be sprayed at a level of approximately 15 to 30 grams per square meter of fabric, and the fabric is then dried to crosslink the binder. The formulation can be sprayed on both sides of

35

the fabric, in which case the amount of formulation sprayed would be between 7.5 and 15 grams per square meter. The binder content of fabric is between 15 and 25 grams per square meter on a dry basis. The amount of PHMB in the formulation applied to the fabric is from 0.05 to 0.40 grams per square meter of fabric on a dry basis.

The amount of antimicrobial agent in the binder formulation is approximately .25% to 2% based on weight. The presence of the antimicrobial in the fabric in amounts greater than 0.40 grams per square meter can result in a saline extraction level of greater than 80 parts per million, which is not desirable.

As indicated above, if it is desirable to maintain the absorbent properties of the fabric, a rewetting agent is included in the formulation. A standard test for absorption is to take a 12" x 12" piece of the fabric to be tested and apply it to a surface at a 45° angle. Forty (40) milliliters of water are then dripped onto the surface of the fabric in a 40 second time period. If no liquid rolls down and off the fabric, the absorbency of the fabric is considered to be acceptable.

The determination of the extraction levels of the PHMB from the fabric by saline is performed in the following manner. A physiological saline solution (0.9% salt concentration) is heated to 40°C in an oven. Samples of the fabric to be tested are cut into 1" squares and placed in a jar with 15 milliliters of the heated solution for each 1 gram sample of fabric. The samples are allowed to wet evenly and held for five minutes with an occasional mixing. The liquid is then removed from the container and tested with the appropriate agent for the antimicrobial. The solutions for PHMB are 1.N sodium hydroxide, cetyl trimethyl ammonium bromide, isopropyl alcohol and alkaline sodium hydrobromate. After the fabric has been extracted,

the reagents are added to a flask which contains the extract and the absorbence at 428 nm. against a blank solution by spectrophotometric determination is made. The amount of PHMB can be directly determined by comparing the  
5 absorbence of tested solution with that of a standard.

The bactericidal efficacy of the fabric is tested in vitro according to the following technique. Samples of the fabric to be tested are cut into 1" squares and placed in  
10 individual petri dishes. Suspensions of the test organisms are prepared using sheep's blood as a diluent with the test organism at a concentration of approximately  $1 \times 10^5$  viable cells per ml. The inoculum at a rate of 0.2 ml is then added to the center of each sample square. The  
15 samples are placed in a high humidity chamber and removed after predetermined exposure times, as shown in the subsequent table. At the end of the exposure time, the samples are placed in a tube with a neutralizer and saturated. The tubes are then vortexed to insure removal  
20 of any surviving bacteria from the test sample. For each tube, 1 ml of neutralizer is placed in a petri dish and poured with molten TSA agar. These petri dishes are then incubated at 37°C for 48 hours, and the colony count is determined. In order to be an acceptable antinicrobial  
25 for the surface of the surgical drape, the  $\log_{10}$  decrease in the bacteria should be at least 3  $\log_{10}$ . A 3  $\log_{10}$  decrease would indicate that 99.9% of the bacteria have been destroyed.

30

Example I

The following Table I shows the log kill against various organisms at 30 and 60 minutes for the material of the present invention as well as controls. The fabric was a  
35 nonwoven fabric containing rayon and woodpulp fibers. The binder containing the antimicrobial was sprayed on both

-11-

sides of the fabric. The binder was a Hycar acrylate binder which contains an anionic surfactant or a 70-30 ethylene vinyl acetate copolymer dispersed with a nonionic surfactant. The bactericidal efficacy was tested by the method set forth above. Table I clearly indicates the bactericidal efficacy of the present invention and also shows that the use of a binder which contains an anionic surfactant cannot be used. Lexaine C is a cocamidopropyl betaine.

Example II

5 Samples of a nonwoven fabric made with a mixture of rayon and woodpulp fibers were treated with a binder formulation containing PHMB as an antimicrobial. The binder formula-  
tion contained the following (on a dry basis):

	ethylene vinyl acetate copolymer	86.35
	PHMB	0.80
	Lexaine C	1.44
10	NH <sub>4</sub> Cl	0.57

15 The formulation was applied as a 19% solution in water at a rate of approximately 20 grams per square meter of fabric. Three different samples of the fabric were tested for bactericidal activity against various bacteria,  
identified in Table II, using Test AATCC-100 in the presence of sheep's blood. A control which was the same fabric without the PHMB was also tested. These were  
20 tested against various organisms, as shown in Table II. The examination of data in Table II shows that the product of the present invention will kill over 99% of bacteria according to the test results.

Example IV

30

This example shows the use of PHMB in repellent-treated, nonwoven fabrics. Samples of unbonded webs were treated with a binder formulation which contained PHMB and a silicone-based repellent finish. The binder formulation

35 contained the following ingredients in parts by weight:

0136900

-16-

	<u>Wet</u>	<u>Dry</u>
Ethylene vinyl acetate copolymer	450	225
PHMB	6.5	1.3
Lexaine C	4.8	1.4
Silicone repellent finish	4.6	4.6

5

The formulation was applied to a nonwoven fabric at the rate of 19.6 grams per square meter on a wet basis. The repellent add-on on a dry basis was 0.42 grams per square meter. The resultant fabric was tested for repellency and found to be water repellent. The fabric was tested for bactericidal activity against *P. aeruginos* and resulted in a 99.5% kill of the bacteria.

10

CLAIMS:

1. A surgical drape having antimicrobial properties comprising a nonwoven fabric bonded with a binder substantially free of anionic surfactants and containing from 0.05 to 0.40 grams per square meter of a polyhexamethylene biquanide hydrochloride as an antimicrobial agent, the saline extraction of the antimicrobial from the fabric by physiological saline being less than 80 parts per million.
2. The surgical drape of Claim 1 in which the nonwoven fabric has a weight of from 40 to 100 grams per square meter.
3. The surgical drape of Claim 1 or Claim 2 in which the binder is an ethylene vinyl acetate copolymer containing approximately 70% ethylene and 30% vinyl acetate.
4. The surgical drape of Claim 3 in which the binder is a dispersion in polyvinyl alcohol prior to being applied to the drape.
5. The drape of any one of Claims 1 to 4 in which the binder is applied to the fabric in an amount of from 15 to 25 grams per square meter.
6. The surgical drape of any one of Claims 1 to 5 containing a surfactant as a rewetting agent in an amount of from 0.25 to 0.50 grams per square meter.
7. The surgical drape of any one of Claims 1 to 6 in which the antimicrobial is present in an amount of 0.15 grams per square meter.

-18-

8. A method of preparing a nonwoven fabric having antimicrobial properties and suitable for use as a surgical drape comprising applying to a preformed web of unbonded fibers an aqueous binder formulation containing:

5 a) from 95% to 98% by weight of an ethylene vinyl acetate copolymer binder substantially free of anionic surfactant;

10 b) from 0.25% to 2% by weight of a polyhexamethylene biguanide hydrochloride,

said binder being applied to said web in an amount of from 15 to 30 grams per square meter of fabric.

15 9. The method of Claim 8 in which the binder also contains from 1% to 2% by weight of cocamidopropyl betaine.
